July 19, 2021

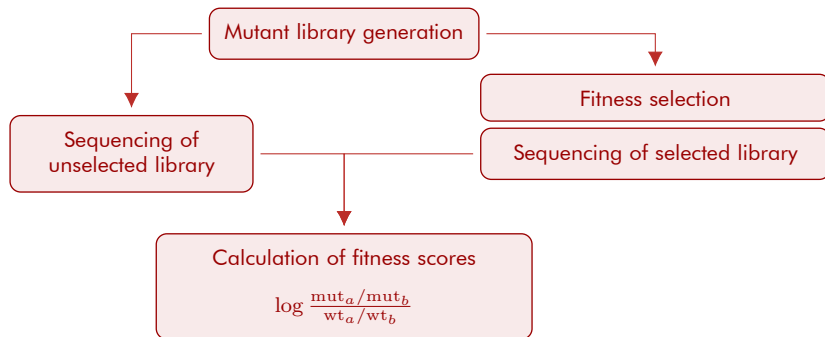

Single Amino Acid Variants

A mutation that replaces exactly one amino acid in a protein

Deep Mutational Scanning

A high-throughput technique for obtaining fitness information on a large number of mutations in parallel

Why is it useful?

- ▶ Targeted medical treatments
- ▶ Protein engineering

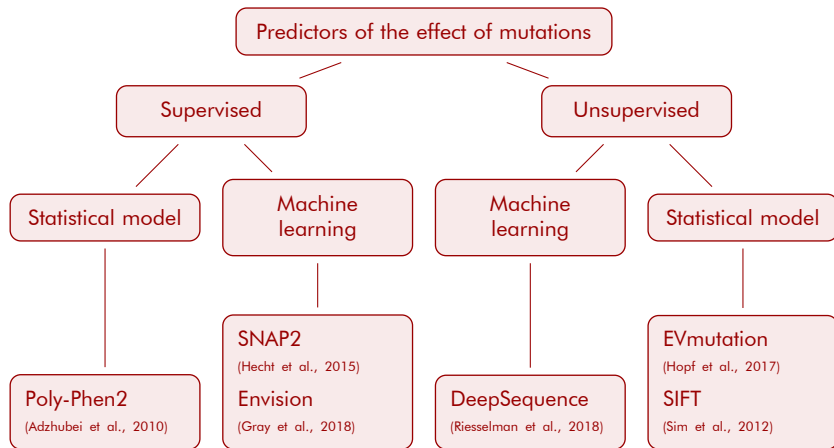

Why is it needed?

- ▶ Experiments are insufficient
- ▶ Experiments are expensive

How can it be done?

- ▶ Machine learning
- ▶ Statistical models

Previous Work in the Field

Among these predictors only Envision was trained on deep mutational scanning data

My Approach

Training Data

I borrowed the training dataset of the predictor Envision (Gray et al., 2018)

Experiments Do Not Agree Much with Each Other

Two independent deep mutational scanning experiments on Ubiquitin are present in the training dataset. Their correlation is low.

Interesting Patterns in Mutation Sensitivity

- ▶ Polar residues seem more tolerant to mutations than hydrophobic residues
- ▶ Proline (P) is the most disruptive residue
- ▶ Tryptophan (W) is hard to replace

Exposure Explains the Mutability of Polar Residues

When filtering by Relative Solvent Accessibility (RSA) apolar residues are **not** more sensitive to mutations than polar residues

Exposed positions (RSA > 0.15)

Mutation from

Average scaled fitness score

Buried positions (RSA ≤ 0.15)

Mutation from

Average scaled fitness score

Buried Residues Are More Conserved

Features Used by the Predictors

All the features are derived from the sequences: I did **not** use any structural information

Mutation identity

EVmutation predictions

(Hopf et al., 2017)

NetsurfP-2 predictions

(Klaussen et al., 2019)

HMMER emission probabilities

(Eddy, 2011)

trRosetta predicted contacts

(Yang et al., 2020)

Single Protein Models

Naive approach

- ▶ A different model trained for each protein
- ▶ Half of the mutations used for testing and half for cross-validation
- ▶ Too good to be true

Single Protein Models

Naive approach

- ▶ A different model trained for each protein
- ▶ Half of the mutations used for testing and half for cross-validation
- ▶ Too good to be true

Segregating protein positions

- ▶ Same as above but mutations in the same position segregated in the training or testing sets
- ▶ Performances are more realistic

Leave-One-Protein-Out (LOPO) Models

- ▶ Models trained on the whole dataset while leaving one protein out
- ▶ For the left-out protein, half of the mutations used for testing and half for validation
- ▶ Spearman correlation coefficient used for evaluation

What I learned

- ▶ The testing strategy is crucial
- ▶ Good performances without structural features
- ▶ Strong variability between datasets
- ▶ Complex models not necessarily better

Ideas for the future

- ▶ Using residue contacts in a graph convolutional neural network
- ▶ Training on more deep mutational scanning studies
- ▶ Finding a better normalization strategy

Questions?
