Deep Mutational Scanning

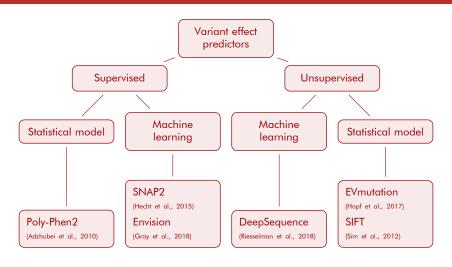

High-throughput technique for obtaining fitness information on a large number of mutations

I Considered Only Single Amino Acid Variants

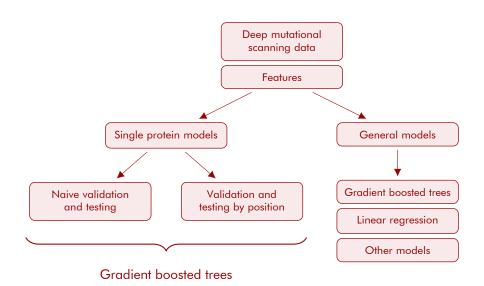

Some Notable Variant Effect Predictors

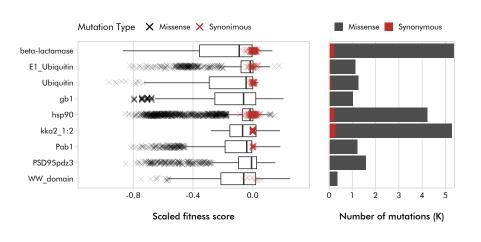

Among these predictors only Envision was trained on deep mutational scanning data

Structure of the Project

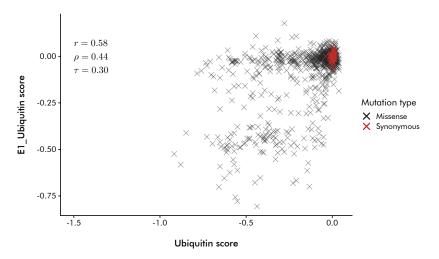

I Used the Training Dataset of Envision (Gray et al., 2018)

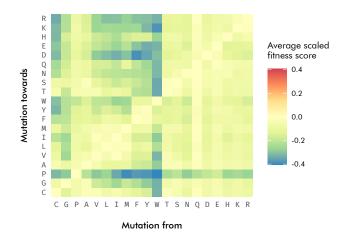

Poor Correlation among Experimental Results

Two independent deep mutational scanning experiments on Ubiquitin are present in the training dataset. Their correlation is low.

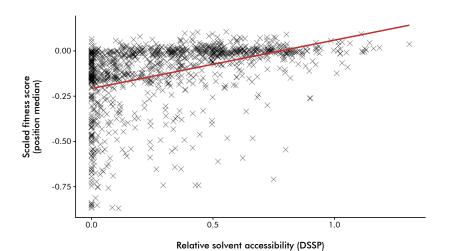

The Identities of the Mutated Residues Are Important

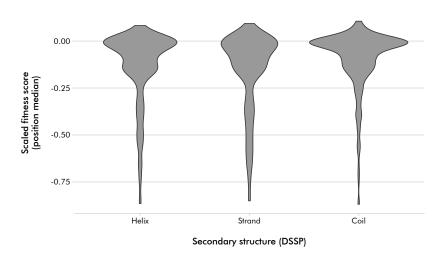

Mutations from polar residues are less detrimental than other mutations. This effect disappears when filtering by relative solvent accessibility (not shown here).

Buried Residues Are More Conserved

Secondary Structure Is **Not** Critical

I Did **Not** Use Structural Information

Mutation identity

Wild-type residue

Mutated residue

EVmutation predictions

(Hopf et al., 2017)

Epistatic model

Independent model

Conservation

Mutation frequency

NetsurfP-2 predictions

(Klausen et al., 2019)

Secondary structure

Solvent accessibility

Disorder

Torsion angles

HMMER emission probabilities

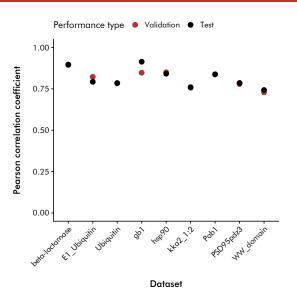

(Eddy, 2011)

trRosetta predicted contacts

(Yang et al., 2020)

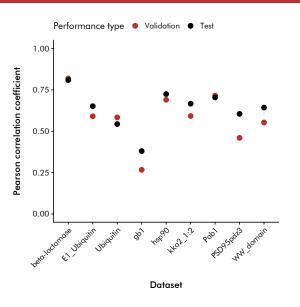

Centrality metrics

Single Protein Models with Naive Testing

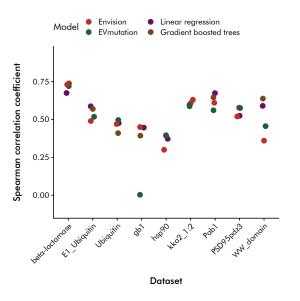

- Half of the mutations in a protein randomly set aside for testing
- Hyperparameters optimized in the remaining half with 5-fold cross-validation
- Good results but likely overfitting the testing set

Single Protein Models with Testing by Position

- Half of the mutations in a protein set aside for testing but avoiding mutations in the same protein position to end up in different splits
- ► Hyperparameters optimized in the remaining half with 5-fold cross-validation
- Performance more realistic

Leave-One-Protein-Out (LOPO) Models

- For the left-out protein, half of the mutations used for testing
- Spearman correlation coefficient used for evaluation
- Small difference among gradient boosted trees and linear regression
- Performances comparable to those of Envision

Discussion

Complex models do not improve much on linear regression

There is strong variability between datasets

Unsupervised models perform similarly to supervised models

How validation and testing are performed is crucial

Performances on par with other predictors can be reached without structural features

Future Directions

Unsupervised models seem promising and may be worth exploring more

Training on more deep mutational scanning studies

Tuning the set of features

Using residue contacts in a graph convolutional neural network

Finding a better normalization strategy for the scores from different experiments

When filtering by Relative Solvent Accessibility (RSA) apolar residues are **not** more sensitive to mutations than polar residues
